Hydra: A Chip Multiprocessor

Hot Chips 1999

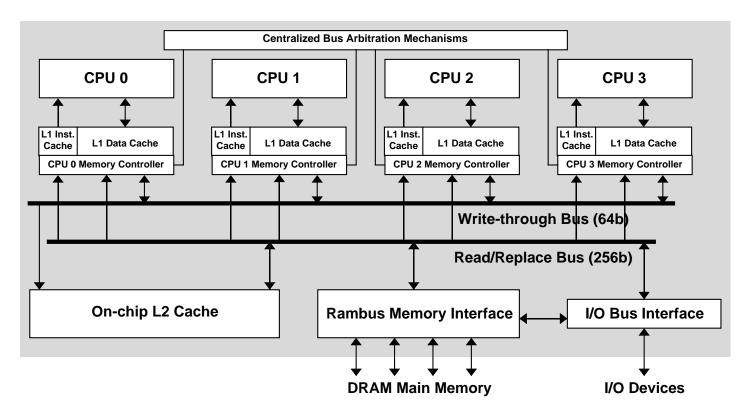

Hydra: A CMP

- A CMP offers implementation benefits
 - High-speed signals are localized in individual CPUs
 - A proven CPU design may be replicated across the die
- Overcomes diminishing performance/ transistor return problem in uniprocessors
 - On parallelized programs
 - With multiprogrammed workloads
- Fast inter-processor communication eases parallelization of code

The Basic Hydra CMP

Hot Chips 1999

Hydra: A CMP

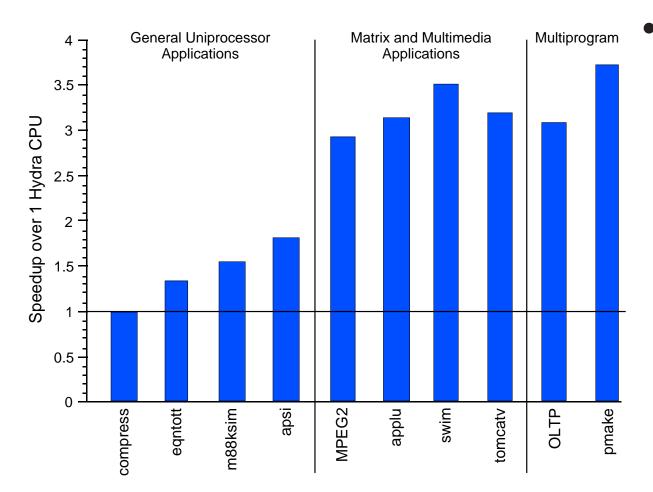

- 4 processors and secondary cache on a chip
- 2 buses connect processors and memory
- Coherence: writes are broadcast on write bus

Parallel Performance

Hot Chips 1999

Hydra: A CMP

- Varying levels of performance
 - Multiprogrammed workloads work well
 - Very parallel apps (matrix-based FP and multimedia) are excellent
 - Acceptable only with a few less parallel (i.e. integer) apps

Problem: Parallel Software

Hot Chips 1999

- Current parallel software is limited
 - Supercomputing applications
 - Server applications (mostly databases)
- Traditional auto-parallelization is limited — Works for some dense matrix Fortran applications
- Many applications only hand-parallelizable

 Parallelism may exist in algorithm, but code hides it
 Compilers must *statically* verify parallelism
 Pointer disambiguation is a major problem for this!
- Can hardware help the situation?

Solution: Data Speculation

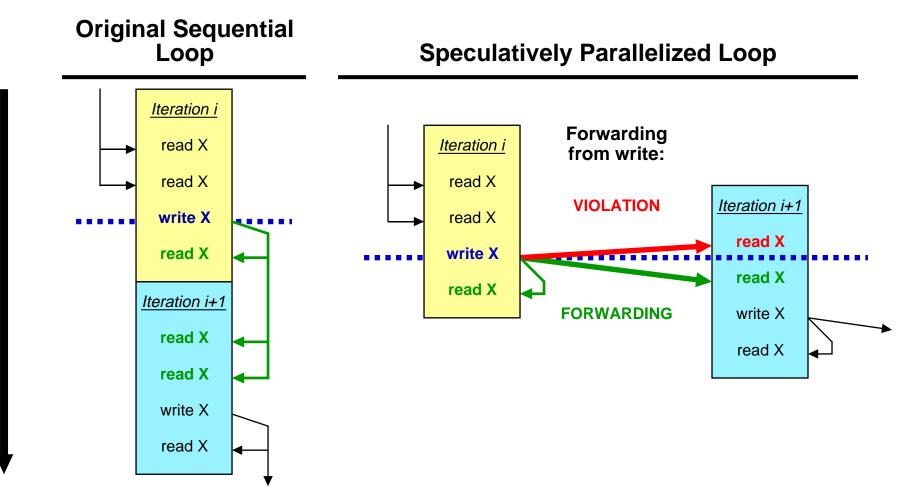

Hot Chips 1999

- Data speculation enables parallelization without regard for data dependencies
 - Normal sequential program is broken up into threads
 - Speculative threads are now run in parallel on CPUs
 - Speculation hardware ensures correctness
- Parallel software implications
 - Loop parallelization is now *easily automated*
 - More "arbitrary" threads are possible (subroutines)
 - Add synchronization only for performance
- Speculation support mechanisms
 - Speculative thread control mechanism
 - 4 memory system requirements

Memory Requirements I

Hot Chips 1999

Speculation Support

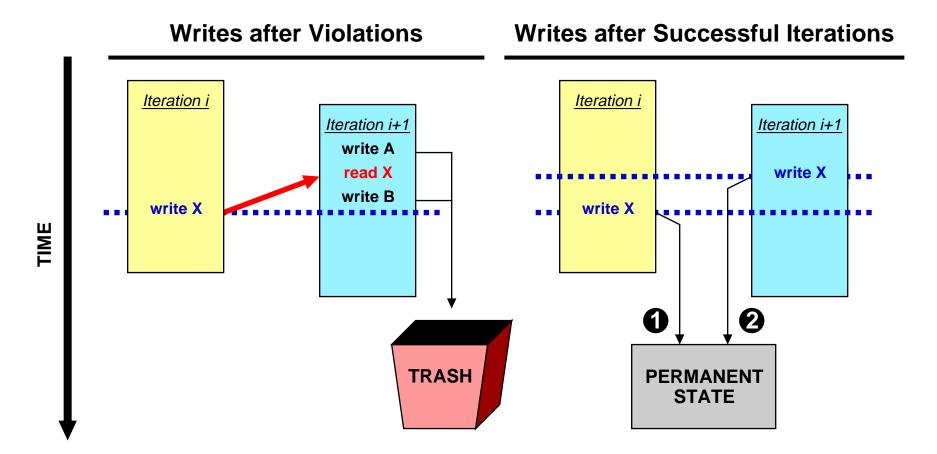

Forward data between parallel threads
 Detect violations when reads occur too early

TIME

Memory Requirements II

Hot Chips 1999

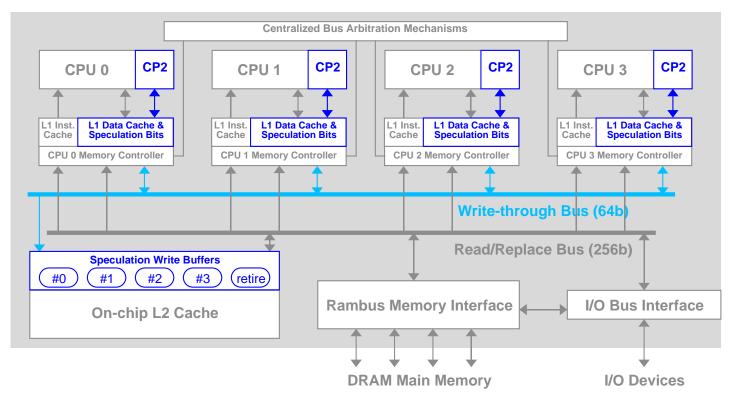

Speculation Support

Safely discard bad state after violations
 Retire speculative writes in the correct order

Hydra Speculation Support

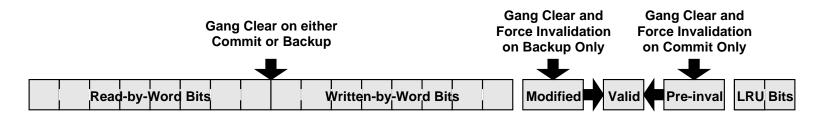

Hot Chips 1999

- 1. Write bus & L2 buffers provide forwarding
- 2. "Read" L1 tag bits set to detect violations
- 3. "Dirty" L1 bits & L2 buffers allow backup
- 4. L2 buffers reorder & retire speculative state
- Speculation coprocessors to control threads

L1 Cache Tag Details

Hot Chips 1999

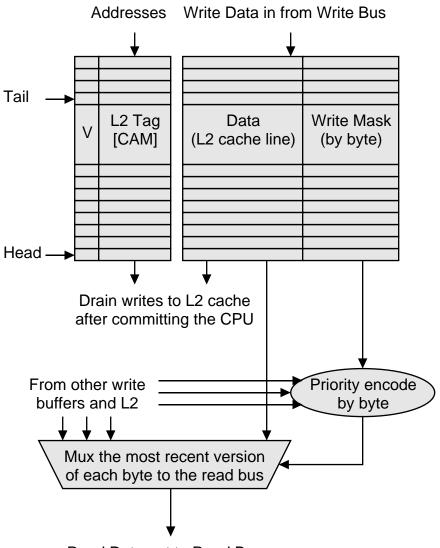

- Speculation requires 4 extra types of bits
 - Read-by-word: Allow violation detection
 - Written-by-word: Allow memory renaming
 - Modified: Allow us to back up after violations
 - **Pre-invalidation:** Allow us to commit and advance
- Special circuits are required in the array
 - Gang clear of all bits on commits and backups
 - Set modified bits cause valid bits to clear on backups
 - Set pre-inval bits cause valid bits to clear on commits

L2 Buffer Details

Hot Chips 1999

- Speculative writes are held here until commit time
 - Collected by cache line
 - CAM tag array, tail pointer
 - Byte write mask for each line
 - Drains into L2 when complete
 - Size of another pair of L1s
- Reads are tricky
 - Line read from L2 cache
 - Any data from "earlier" buffers is substituted, if present
 - Requires byte-by-byte priority encoding & muxing

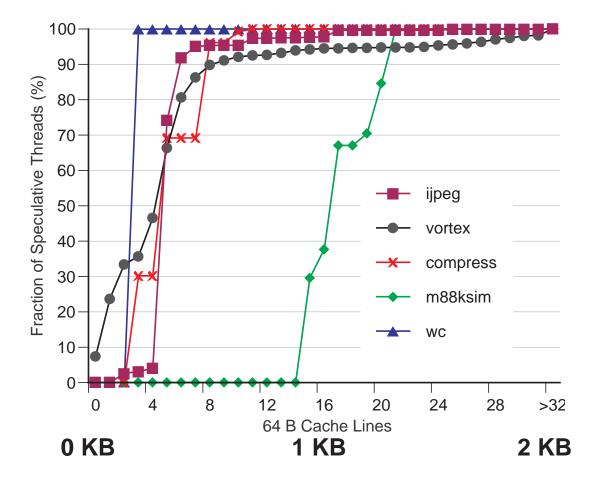

Read Data out to Read Bus

L2 Data Buffering

Hot Chips 1999

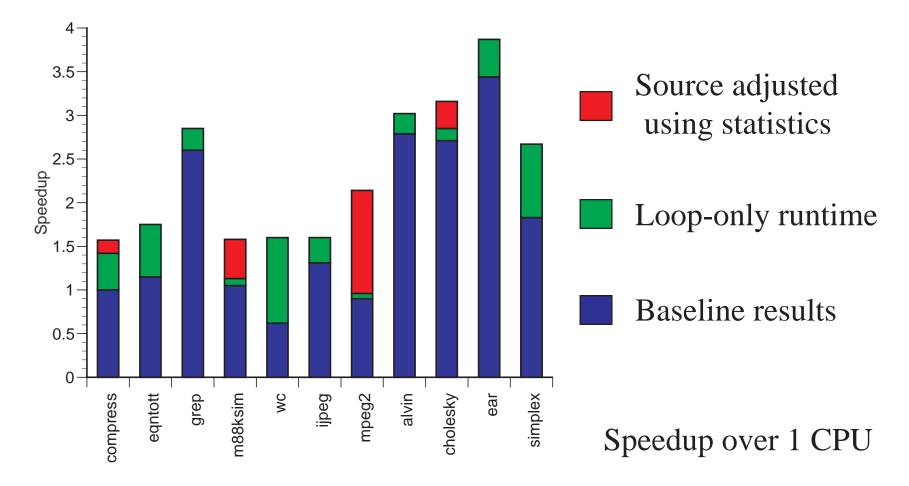

- Small buffers are sufficient
 - We used a fully associative line buffer
 - < 1 KB per thread captures most writes

Speculation Performance

Hot Chips 1999

- Results representative of entire uniprocessor applications
- Simulated with accurate modeling of Hydra's memory
- Enhanced performance versions were presented at ICS 99

Prototype Overview

Hot Chips 1999

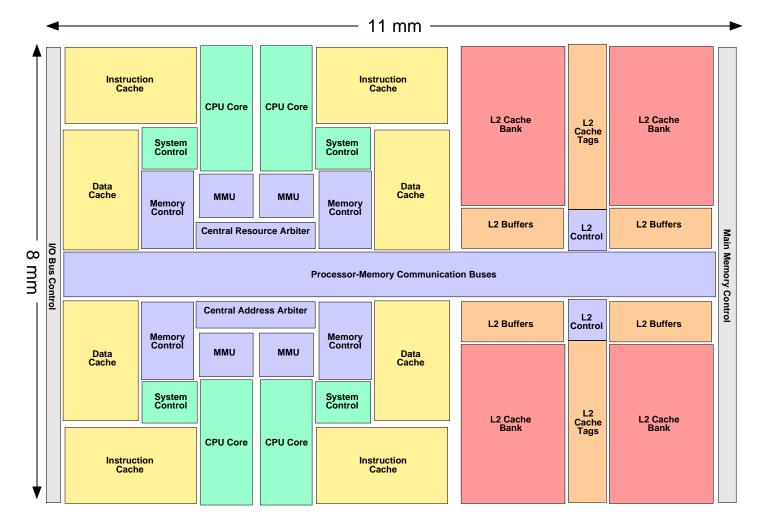

Prototype Implementation

- CPU core and cache macros
- Speculative coprocessor
 - Speculative memory reference controller
 - Speculative interrupt screening mechanism
 - Statistics mechanisms for performance evaluation and to allow feedback for code tuning
- Memory system
 - Read and write buses
 - Controllers for all resources
 - On-chip L2 cache
 - Simple off-chip main memory controller
 - I/O and debugging interface

Prototype Layout

Hot Chips 1999

Prototype Implementation

Hardware design based on IDT RC32364
 — 88 mm² in 0.25µm process with 8K I/8K D/~128K L2

Prototype Issues

Hot Chips 1999

Prototype Implementation

- 250 MHz clock rate target
 - Most critical parts are primarily in existing cores
 - Pipelining in most of the memory system may change to meet timing requirements
- Central Bus Arbitration Mechanism
 - High fan-in and fan-out gates
 - Single cycle operation required here
- Drivers for long buses
- Road Map
 - Finish synthesizable Verilog, this summer
 - Finish circuit design and layout, H2 '99
 - Complete verification and tapeout, H1 '00

Conclusions

Conclusions

- Hydra offers many advantages
 - Great performance on parallel applications
 - Good performance on most uniprocessor applications using data speculation mechanisms
 - Scalable, modular design
 - Speculative hardware does not add much to cost, yet greatly increases the number of parallel applications
- Prototype implementation
 - Will work out implementation details
 - Will allow us to validate our performance evaluations
 - Will provide a platform for application and compiler development
